### 1 Logistic Regression

We begin with a review of binary classification and logistic regression. To this end, suppose we have we have training examples  $x \in \mathbb{R}^{m \times n}$  with binary labels  $y \in \{0,1\}^{1 \times n}$ . We desire to train a model which yields an output a which represents

$$a = \mathbb{P}(y = 1|x).$$

To this end, let  $\sigma: \mathbb{R} \to (0,1)$  denote the sigmoid function, i.e.,

$$\sigma(z) = \frac{1}{1 + e^{-z}},$$

and let  $w \in \mathbb{R}^m$ ,  $b \in \mathbb{R}$ , and let

$$a = \sigma(w^T x + b).$$

To analyze the accuracy of model, we need a way to compare y and a, and ideally this functional comparison can be optimized with respect to (w, b) in such a way to minimize the error. To this end, we note that

$$\mathbb{P}(y|x) = a^y (1-a)^{1-y},$$

or rather

$$\mathbb{P}(y=1|x)=a, \qquad \mathbb{P}(y=0|x)=1-a,$$

so  $\mathbb{P}(y|x)$  represents the corrected probability. Now since we want

$$a \approx 1$$
 when  $y = 1$ ,

and

$$a \approx 0$$
 when  $y = 0$ ,

and  $0 \le a \le 1$ , any error using differences won't be refined enough to analyze when tuning the model. Moreover, since introducing the sigmoid function, our usual mean-squared-error function won't be convex. This leads us to apply the log function, which when restricted to (0,1) is a bijective mapping of  $(0,1) \to (-\infty,0)$ . This leads us to define our log-loss function

$$L(a, y) = -\log(\mathbb{P}(y|x))$$
  
=  $-\log(a^{y}(1-a)^{1-y})$   
=  $-[y\log(a) + (1-y)\log(1-a)],$ 

and finally, since we wish to analyze how our model performs on the entire training set, we need to average our log-loss functions to obtain our cost function  $\mathbb J$  defined by

$$\mathbb{J}(w,b) = \frac{1}{n} \sum_{j=1}^{n} \mathbb{L}(a_j, y_j) 
= -\frac{1}{n} \sum_{j=1}^{n} \left[ y_j \log(a_j) + (1 - y_j) \log(1 - a_j) \right] 
= -\frac{1}{n} \sum_{j=1}^{n} \left[ y_j \log(\sigma(w^T x_j + b)) + (1 - y_j) \log(1 - \sigma(w^T x_j + b)) \right].$$

#### 1.1 The Gradient

To compute the gradient of our cost function  $\mathbb{J}$ , we first write  $\mathbb{J}$  as a sum of compositions as follows: We have the log-loss function considered as a map  $\mathbb{L}:(0,1)\times\mathbb{R}\to\mathbb{R}$ ,

$$\mathbb{L}(a, y) = -[y \log(a) + (1 - y) \log(1 - a)],$$

we have the sigmoid function  $\sigma: \mathbb{R} \to (0,1)$  with  $\sigma(z) = a$  and  $\sigma'(z) = a(1-a)$ , and we have the collection of affine-functionals  $\phi_x: \mathbb{R}^m \times \mathbb{R} \to \mathbb{R}$  given by

$$\phi_x(w,b) = w^T x + b,$$

for which we fix an arbitrary  $x \in \mathbb{R}^m$  and write  $\phi = \phi_x$ , and set  $z = \phi(w, b)$ . Finally, we introduce the auxiliary function  $\mathcal{L} : \mathbb{R}^m \times \mathbb{R} \to \mathbb{R}$  given by

$$\mathcal{L}(w,b) = \mathbb{L}(\sigma(\phi(w,b)), y).$$

Then by the chain rule, we have that

$$d\mathcal{L} = d_a \mathbb{L}(a, y) \circ d\sigma(z) \circ d_w \phi(w, b)$$

$$= \left[ -\frac{y}{a} + \frac{1 - y}{1 - a} \right] \cdot a(1 - a) \cdot \begin{bmatrix} x^T & 1 \end{bmatrix}$$

$$= \left[ -y(1 - a) + a(1 - y) \right] \cdot \begin{bmatrix} x^T & 1 \end{bmatrix}$$

$$= (a - y) \begin{bmatrix} x^T & 1 \end{bmatrix}$$

Composition turns into matrix multiplication in the tangent space. Moreover, since in Euclidean space, we have that  $\nabla f = (df)^T$ , and hence that

$$\nabla \mathcal{L}(w, b) = (a - y) \begin{bmatrix} x \\ 1 \end{bmatrix},$$

or rather

$$\partial_w \mathbb{L}(a, y) = (a - y)x, \qquad \partial_b \mathbb{L}(a, y) = a - y.$$

Finally, since our cost function  $\mathbb J$  is the sum-log-loss, we have by linearity that

$$\partial_w \mathbb{J}(w, b) = \frac{1}{n} \sum_{j=1}^n (a_j - y_j) x_j$$
$$= \frac{1}{n} ((a - y) \cdot x^T)^T$$
$$= \frac{1}{n} x \cdot (a - y)^T$$

and

$$\partial_b \mathbb{J}(w,b) = \frac{1}{n} \sum_{j=1}^n (a_j - y_j).$$

#### 1.1.1 Vectorization in Python

Here we include the general code to train a model using logistic regression without regularization and without tuning on a cross-validation set.

```
1 import copy
з import numpy as np
5 def sigmoid(z):
      Parameters
       z : array_like
10
      Returns
11
12
       sigma : array_like
13
14
15
       sigma = (1 / (1 + np.exp(-z)))
16
       return sigma
17
18
```

```
19 def cost_function(x, y, w, b):
      Parameters
21
      _____
22
      x : array_like
23
          x.shape = (m, n) with m-features and n-examples
24
      y : array_like
25
          y.shape = (1, n)
26
27
      w : array_like
          w.shape = (m, 1)
28
      b : float
30
      Returns
31
       -----
32
      J : float
33
          The value of the cost function evaluated at (w, b)
34
      dw : array_like
35
          dw.shape = w.shape = (m, 1)
36
          The gradient of J with respect to w
37
      db : float
38
          The partial derivative of J with respect to b
39
40
41
      # Auxiliary assignments
42
      m, n = x.shape
43
      z = w.T @ x + b
      assert z.size == n
45
      a = sigmoid(z).reshape(1, n)
      dz = a - y
47
      # Compute cost J
49
      J = (-1 / n) * (np.log(a) @ y.T + np.log(1 - a) @ (1 - y).T)
50
51
      # Compute dw and db
      dw = (x @ dz.T) / m
53
      assert dw.shape == w.shape
54
      db = np.sum(dz) / m
55
56
      return J, dw, db
57
58
  def grad_descent(x, y, w, b, alpha=0.001, num_iters=2000, print_cost=False):
